1 Theory behind Discretization

Figure 1: Discretization process

We now consider a discretization of a curve. Index the points on the curve by $\mathcal{I} = \{1, 2, \dots, M\}$, such that points are given by $\{\gamma_1, \gamma_2, \dots, \gamma_M\}$

Using the similar notation to the paper by Yu, Schumacher, and Crane, for edge $I = \{\gamma_i, \gamma_j\} \in E$ and for function $u : \mathbb{R}^3 \rightarrow \mathbb{R}$

- $l_I := |\gamma_i - \gamma_j|$
- $T_I := \frac{\gamma_j - \gamma_i}{l_I}$
- $\mathbf{x}_I := \frac{\gamma_i + \gamma_j}{2}$
- $u_I := \frac{u_i + u_j}{2}$
- Syntactic sugar: $u_i \equiv u(\gamma_i)$
- $u[I] := \begin{pmatrix} u_i \\ u_j \end{pmatrix}$

1.1 Discrete Energy

The naïve discretization of $\mathcal{E}_\beta^\alpha := \iint_{M^2} k_\beta^\alpha(\gamma(x), \gamma(y), T(x)) \, dx_\gamma \, dy_\gamma$ where $k_\beta^\alpha(p, q, T) := \frac{|T \times (p - q)|^\alpha}{|p - q|^\beta}$ is given by

$$\sum_{I \in E} \sum_{J \in E} \int_{\bar{I}} \int_{\bar{J}} k_\beta^\alpha(\gamma(x), \gamma(y), T_I) \, dx_\gamma \, dy_\gamma \quad (1)$$

However, in a polygonal curve (hence the discretized curve), (1) is ill-defined.

Figure 2: Near each vertex, the integrand is unbounded.

So resolve this by removing the two neighboring edges.¹ Also approximate the kernel by the average of the kernel evaluated at each pair of appropriate edges (total: 4)

$$\hat{\mathcal{E}}_{\beta}^{\alpha} := \sum_{I,J \in E, I \cap J = \emptyset} \left(\hat{k}_{\beta}^{\alpha} \right)_{I,J} l_I l_J \quad (2)$$

$$\left(\hat{k}_{\beta}^{\alpha} \right)_{I,J} := \frac{1}{4} \sum_{i \in J, j \in J} k_{\beta}^{\alpha} (\gamma_i, \gamma_j, T_I) \quad (3)$$

2 Discrete Gradient Flow in L^2 for Closed Loop

Suppose a curve is discretized as position vectors: x_1, x_2, \dots, x_M (and $x_{M+1} := x_1$).

Also denote the edge from x_i to x_{i+1} as I_i (as opposed to the previous section).

¹In the limit, the contribution from this removed edge goes to zero.

The **discretized energy** E can be expressed as:

$$E = \sum_{i=1}^M \sum_{\substack{j=1 \\ |j-i|>1}} k_{i,j} \|x_{i+1} - x_i\| \|x_{j+1} - x_j\| \quad (4)$$

$$k_{i,j} = \frac{1}{4} (k_{\beta}^{\alpha}(x_i, x_j, T_i) + k_{\beta}^{\alpha}(x_i, x_{j+1}, T_i) + k_{\beta}^{\alpha}(x_{i+1}, x_j, T_i) + k_{\beta}^{\alpha}(x_{i+1}, x_{j+1}, T_i)) \quad (5)$$

Figure 3: Kernel $k_{i,j}$ computation

Recall the definition of differential, gradient, and gradient flow.

Definition 1 (Differential). Given functional $\mathcal{E}(\gamma)$, the **differential** is defined as:

$$d\mathcal{E}|_{\gamma}(u) = \lim_{\epsilon \rightarrow 0} \frac{1}{\epsilon} (\mathcal{E}(\gamma + \epsilon u) - \mathcal{E}(\gamma)) \quad (6)$$

Definition 2 (Gradient). Given functional $\mathcal{E}(\gamma)$ and space V , the **gradient** $\text{grad } \mathcal{E}$ is the unique function satisfying the following for any function u :

$$\langle \langle \text{grad } \mathcal{E}, u \rangle \rangle_V = d\mathcal{E}(u) \quad (7)$$

Note that the LHS is a inner product of two vector-valued functions. A natural inner product in L^2 to define is:

$$\langle \langle u, v \rangle \rangle_{L^2} := \int_{\Omega} u \cdot v \, dx \quad (8)$$

Definition 3 (Gradient Flow). Given functional $\mathcal{E}(\gamma)$, the **gradient flow** equation is defined as:

$$\frac{d}{dt}\gamma = -\text{grad } \mathcal{E}(\gamma) \quad (9)$$

Note that $\gamma = (\gamma_x, \gamma_y, \gamma_z)^T \in \mathbb{R}^3$, so it might be clearer to write:

$$\frac{d}{dt} \begin{pmatrix} \gamma_x \\ \gamma_y \\ \gamma_z \end{pmatrix} = \text{grad } \mathcal{E} \left(\begin{pmatrix} \gamma_x \\ \gamma_y \\ \gamma_z \end{pmatrix} \right) \quad (10)$$

Gradient flow equation in L^2 is given by:

$$\dot{x}_i = -\frac{\partial E}{\partial x_i} \quad (11)$$
